

# Gastrointestinal System

## Introduction:

➤ The GIT is arranged as:

1. Gastrointestinal tract	2. Accessory digestive glands
<ul style="list-style-type: none"> <li>It is a <b>continues tube</b> that extends from the mouth to the anus.</li> </ul>	<ul style="list-style-type: none"> <li>Salivary glands.</li> <li>Pancreas.</li> <li>Liver &amp; gall bladder.</li> </ul>

## Functions of GIT:

- 1) **Motility** : propels the ingested food and mixes it with the secretions.
- 2) **Secretions** of the digestive juices and mucus.
- 3) **Digestion** of the ingested foods into absorbable molecules.
- 4) **Absorption** of the nutrients, electrolytes and water from intestinal lumen into blood stream.

# Physiology of Salivation

## Salivary gland

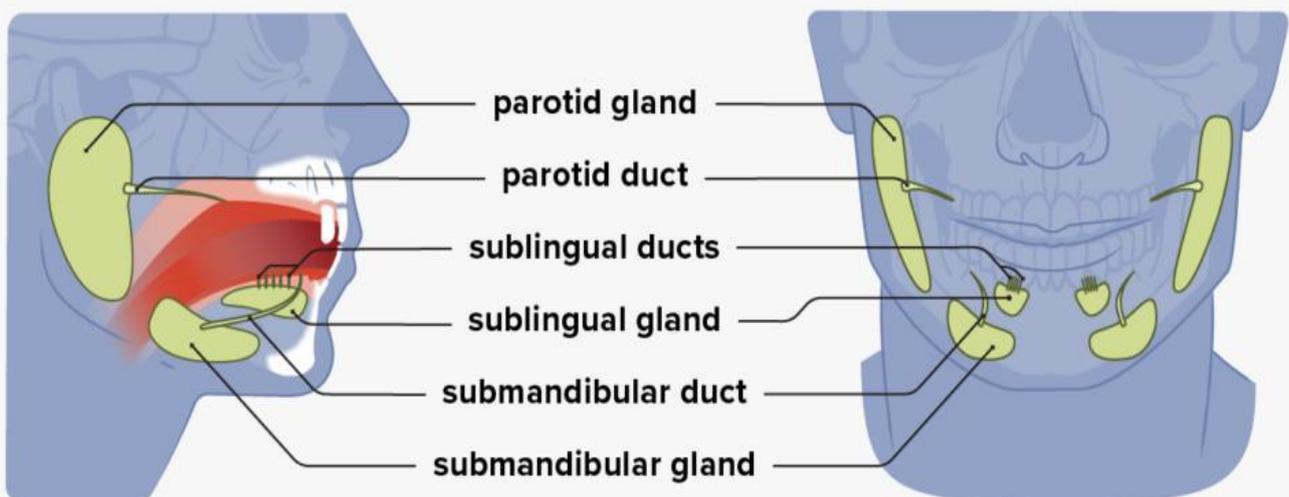

### ▪ Structure:

The principal salivary glands	Small glands
<ul style="list-style-type: none"> <li>• Parotid.</li> <li>• Submandibular.</li> <li>• Sublingual glands.</li> </ul>	<ul style="list-style-type: none"> <li>• Are <b>scattered</b> in the mucous membrane of the <b>buccal cavity</b>.</li> </ul>

### ▪ Principal salivary glands:

	Parotid gland	Sublingual gland	Submandibular gland
<b>% of total secretion</b>	25%	5%	70%
<b>Cells</b>	mainly <b>serous</b> secreting cells	mainly <b>mucous</b> secreting cells.	<b>serous and mucous</b> cells.

### The salivary system

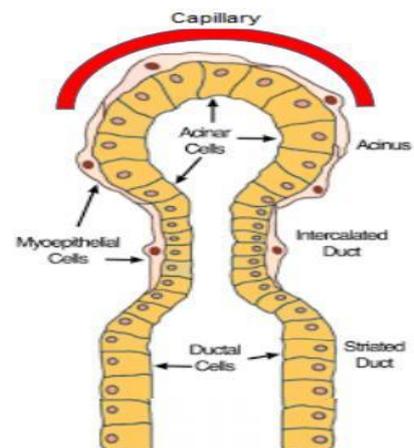

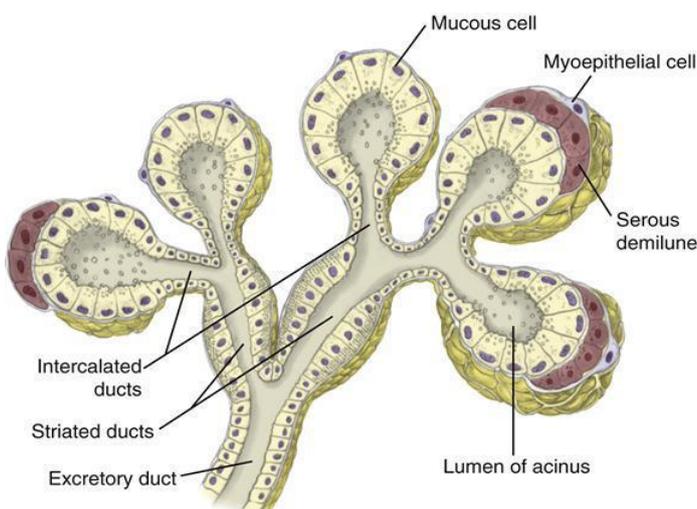

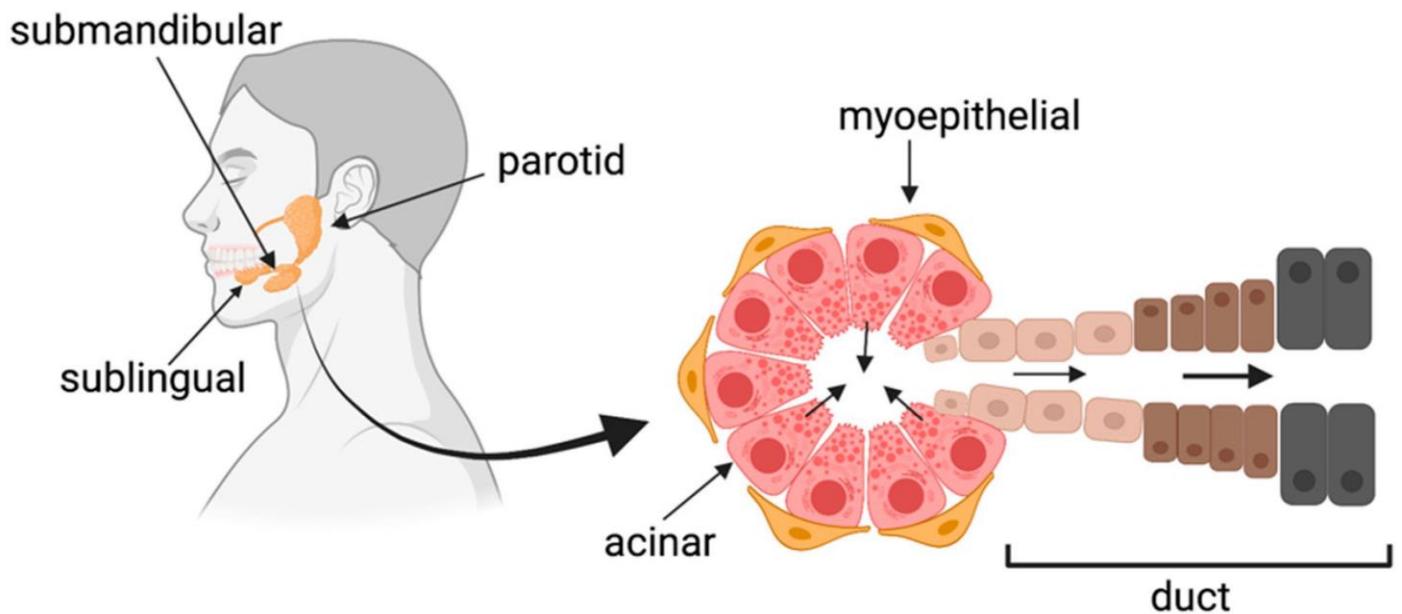

▪ **Salivary Secretions:**

➤ Two main types of protein secretion in saliva:

	Serous secretion	Mucous secretion
Secreted from	Serous cells	Mucous cells
Contains	<b>Ptylaine (alpha amylase) enzyme</b> for digestion of starches	<b>Mucin</b> for lubrication

▪ **Salivon:**

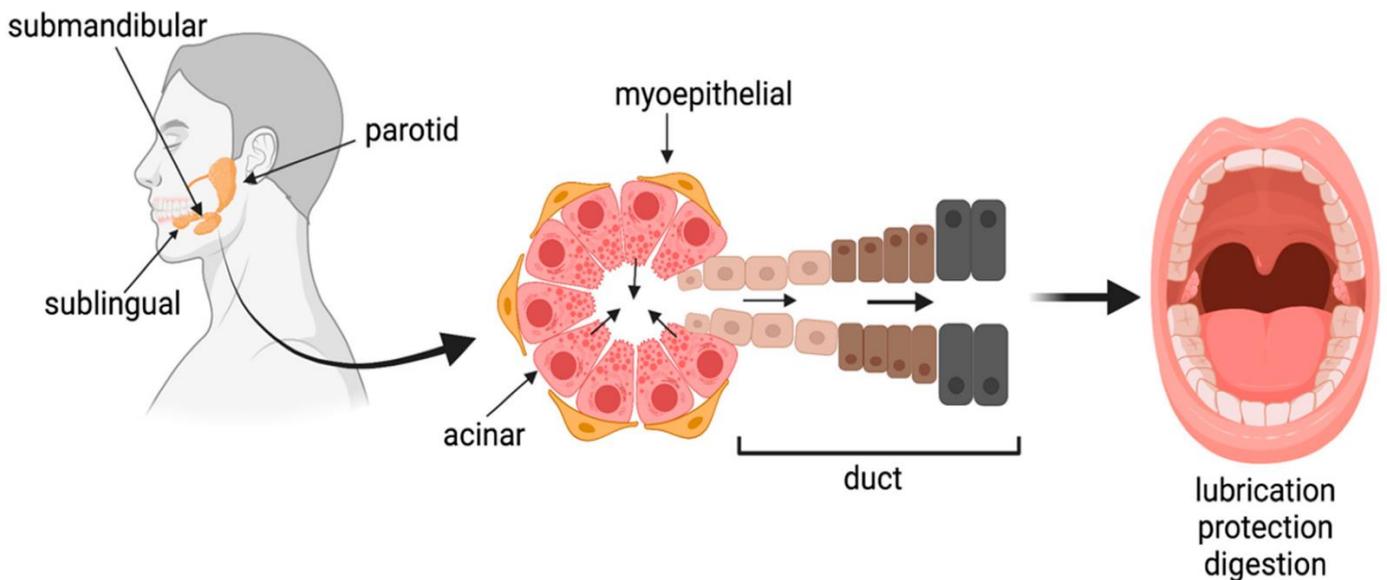

- a group of **secretory acini** and their **ducts** from which each gland is formed.
- The acinar cells empty into the **intercalated duct** which empties into the **striated duct**.

▪ **Composition of saliva:**

- **Volume:** 800-1500 ml/day.
- **PH:** Slightly above 7 during rest.
- **Saliva is composed of:**

<b>Water:</b>	<ul style="list-style-type: none"> <li>• 99%</li> </ul>	
<b>Solids</b>	<ul style="list-style-type: none"> <li>• 1%.</li> <li>• <b><u>Divided into:</u></b></li> </ul>	
	<b>Organic</b>	<b>Inorganic</b>
	<ul style="list-style-type: none"> <li>• <b>Lysozymes</b> which attack bacteria wall</li> <li>• <b>Lactoferrin</b> which binds iron</li> <li>• <b>enzymes</b> (Alpha amylase and lingual lipase).</li> <li>• <b>Mucin</b></li> <li>• <b>Proline-rich proteins</b> that protect tooth enamel</li> <li>• <b>Ig A</b></li> </ul>	<ul style="list-style-type: none"> <li>• Na</li> <li>• K</li> <li>• Cl</li> <li>• HCO<sub>3</sub></li> <li>• Thiocyanate ions which kill bacteria</li> </ul>

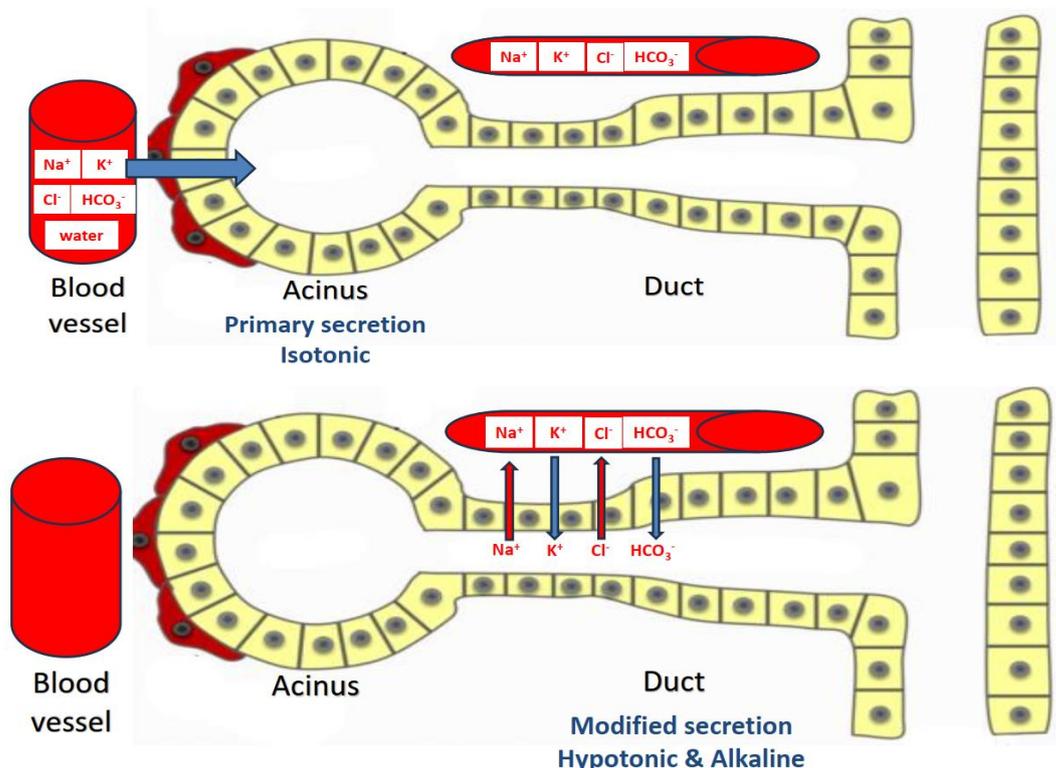

▪ **Formation of saliva:**

➤ The formation of saliva is **an active secretory process.**

➤ It occurs in two stages:

	a) First stage	b) Second stage
<b>Site</b>	It occurs in <b>acini</b> .	It occurs in the <b>salivary duct</b> .
<b>Changes that occur</b>	<ul style="list-style-type: none"> <li>That means, the concentrations of <math>\text{Na}^+</math>, <math>\text{K}^+</math>, <math>\text{Cl}^-</math>, and <math>\text{HCO}_3^-</math> are <b>close to those in plasma.</b></li> </ul>	<ul style="list-style-type: none"> <li><b>Ducts modify the initial saliva by the following processes:</b> <ol style="list-style-type: none"> <li><b>1) Reabsorb <math>\text{Na}^+</math> actively and <math>\text{Cl}^-</math> passively:</b> so, concentrations are lower than plasma.</li> <li><b>2) Secrete <math>\text{K}^+</math> actively and <math>\text{HCO}_3^-</math>:</b> so, concentrations are higher than plasma.</li> </ol> </li> </ul>
<b>Osmolarity</b>	<ul style="list-style-type: none"> <li>The acini secrete primary secretion which is <b>isotonic.</b></li> </ul>	<ul style="list-style-type: none"> <li><b>Modified secretion Hypotonic &amp; Alkaline</b></li> </ul>

▪ What happen if:

There is high flow rate of the saliva	There is low flow rate of the saliva
<ul style="list-style-type: none"> <li>• Saliva is <b>like</b> the primary secretion from acinus.</li> </ul>	<ul style="list-style-type: none"> <li>• Saliva is <b>like</b> the modified secretion in the duct.</li> </ul>
<ul style="list-style-type: none"> <li>• <b>High</b> Na<sup>+</sup> and Cl<sup>-</sup> concentrations.</li> <li>• <b>low</b> K<sup>+</sup> concentration.</li> </ul>	<ul style="list-style-type: none"> <li>• <b>Low</b> Na<sup>+</sup> and Cl<sup>-</sup> concentrations.</li> <li>• <b>high</b> K<sup>+</sup> concentration.</li> </ul>

▪ Mechanism of salivary secretion:

➤ Salivary secretion is **a rapid process**, so it is under nervous control **only**.

	Parasympathetic stimulation	Sympathetic stimulation
<b>Effect</b>	<b>Both increase</b> salivary secretion	
<b>Dominance</b>	<b>Dominant</b>	-----
<b>Origin</b>	Cranial nerves VII and IX	T1 – T3
<b>Nature of secretion</b>	<b>True secretion</b> (Watery and little in enzymes)	<b>Trophic secretion</b> (Little in amount, rich in enzymes)

▪ Phases of salivary secretion:

- a) Cephalic phase
- b) Buccal phase
- c) Gastrointestinal Phase

	A) Cephalic phase	B) Buccal phase	C) Gastrointestinal Phase
<b>Time:</b>	<ul style="list-style-type: none"> <li>Occurs <b>before</b> food enters mouth</li> </ul>	<ul style="list-style-type: none"> <li>Occurs <b>when</b> food enters mouth</li> </ul>	<ul style="list-style-type: none"> <li>Occurs by <b>Irritation of the lower end of the esophagus &amp; stomach or upper intestine</b></li> </ul>
<b>Nature:</b>	<p><u>Conditioned reflex</u></p> <ul style="list-style-type: none"> <li><b>Acquired</b> not inherent.</li> <li>Needs <b>training</b>.</li> <li><b>New connections</b> develop between centers in cerebral cortex &amp; salivary nuclei.</li> </ul>	<p><u>Unconditioned reflex</u></p> <ul style="list-style-type: none"> <li><b>Inherent</b> not acquired</li> <li><b>doesn't</b> need training</li> <li><b>doesn't</b> need intact cerebral cortex.</li> </ul>	<p><u>Unconditioned reflex</u></p> <ul style="list-style-type: none"> <li>Esophageo - salivary reflex</li> <li>gastro – salivary reflex</li> </ul>

## Functions of saliva:

- 1) Keeps the buccal cavity wet, which aids speech and facilitate movements of lips and tongue.
- 2) Acts as solvent for the food particles, to stimulate taste receptors.
- 3) Acts as **diluting medium** for irritating substances.
- 4) Starts the Digestion of the **starch**.
- 5) A **lubricant** which facilitates swallowing.

### 6) It keeps the PH of the mouth about 7:

- To **preserves Calcium** in the teeth.
- **Acidity of the buccal cavity** (e.g., By bacterial action on food remnant) will cause **dissolution of  $Ca^{++}$**  from teeth → **Dental caries**.

### 7) Role of saliva in oral Hygiene:

- A. It contains **Lysozymes** which destroy bacteria.
- B. It contains **IgA** → immunological defense against bacteria and viruses.
- C. **Thiocyanate ions**, which are bactericidal.
- D. Flow of saliva **wash away** the pathogenic bacteria and the food particles.

# Physiology of Swallowing

## Mastication = Chewing

<b>Def:</b>	<ul style="list-style-type: none"><li>• food is broken down into <b>small particles</b> to be swallowed easily.</li></ul>
<b>Mechanism:</b>	<ul style="list-style-type: none"><li>• <b><u>It is a reflex</u></b><ol style="list-style-type: none"><li>1) <b>Presence of food</b> in the mouth causes reflex <b>inhibition</b> of mastication muscles → <b>drop</b> of the lower jaw.</li><li>2) The jaw drop initiates <b>stretch reflex</b> of the jaw muscles → <b>Rebound contraction</b> of these muscles → Elevation of the jaw and closure of the mouth.</li><li>3) The bolus of food is <b>compressed against</b> the linings of the mouth → inhibits the <b>jaw muscles</b> → drop the jaw, and the process is repeated again and again.</li></ol></li></ul>
<b>Functions:</b>	<ol style="list-style-type: none"><li>1. <b>Breakdown of the food into small particles</b> → easy swallowing, decrease the mechanical damage of the mucosa.</li><li>2. <b>It stimulates salivary secretion</b></li><li>3. <b>It stimulate taste and smell receptors.</b></li><li>4. <b>Help digestion, especially fruits and vegetables</b> which contain undigestible cellulose</li></ol>

# Deglutition = Swallowing

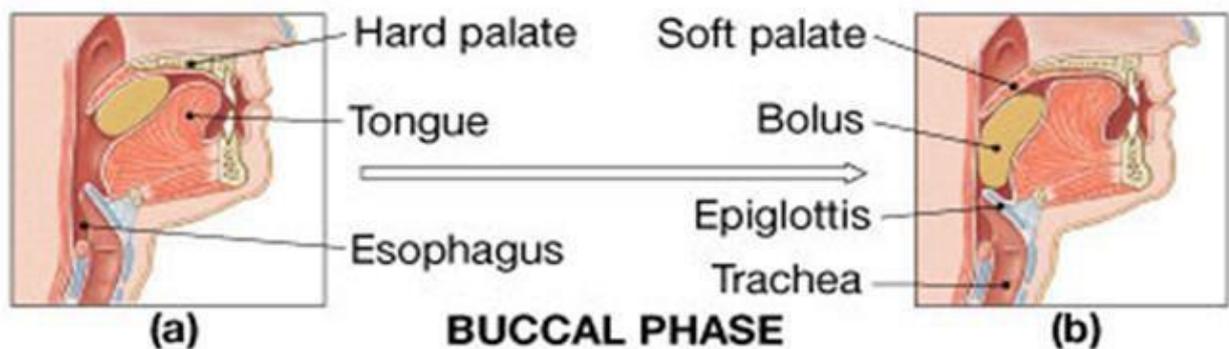

## ▪ **Def:**

➤ The act by which food is transferred from the **mouth cavity** to the **stomach**.

## ▪ **It is divided into 3 phases:**

### **A) Buccal (voluntary) phase**

- The tongue moves **upward and backward** against the palate → push food into the pharynx.
- Once the food reaches the pharynx, the process of swallowing becomes entirely **automatic** and cannot be stopped.

### **B) Pharyngeal (involuntary) phase**

- **Involuntary phase (reflex in nature in which):**

<b>Stimulus</b>	• Presence of food at the back of mouth.
<b>Receptor</b>	• Swallowing receptor area around pharyngeal opening.
<b>Center</b>	• Swallowing center in brain (at medulla oblongata)
<b>Efferent</b>	• 5th, 9th, 10th, 12th cranial nerves.
<b>Effect</b>	• It initiates series of muscular contractions as below:

▪ **Initiate series of muscular contractions:**

**1- Prevent food entrance to the nose through:**

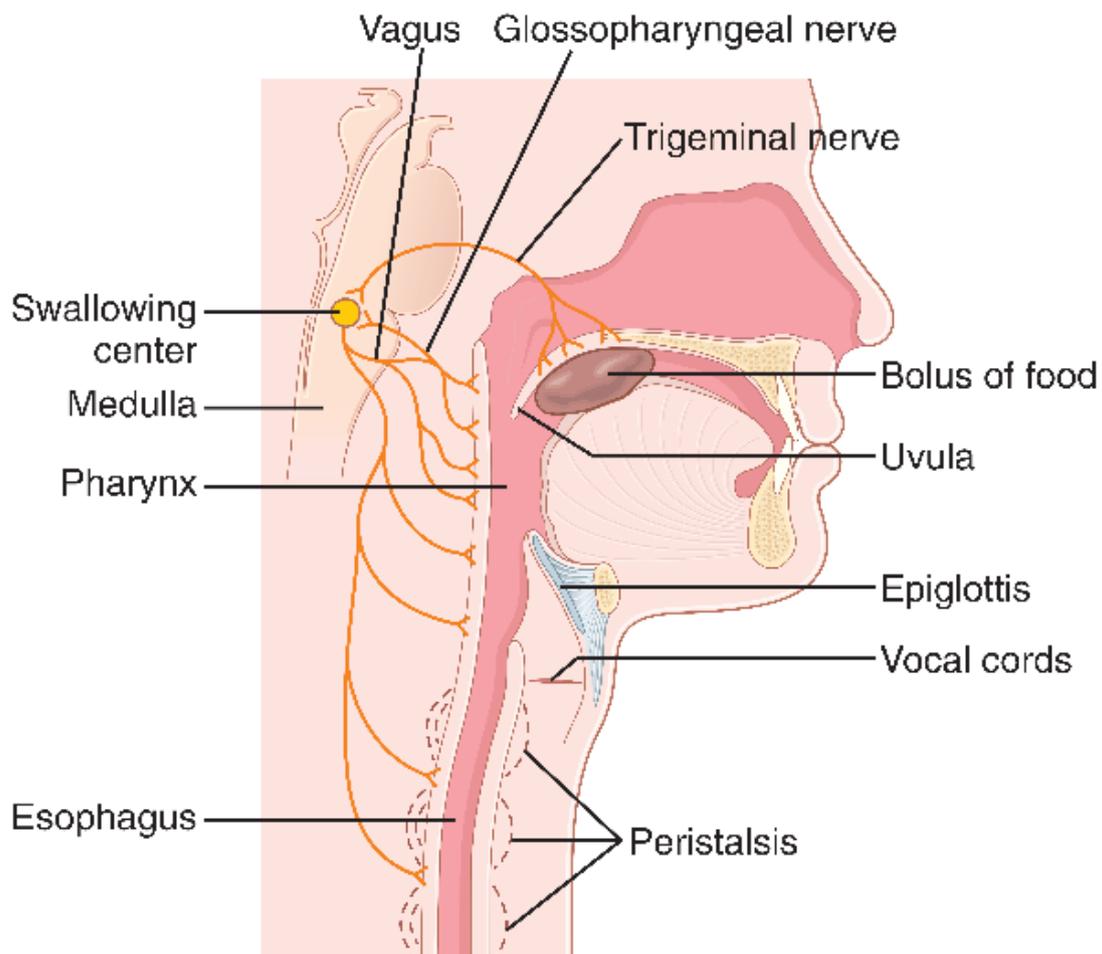

- Pulling the **soft palate** upward to close the **posterior nasal cavity**.

**2- Prevent food entrance to the trachea through:**

- **The vocal cord** are approximated strongly (the most important).
- **The epiglottis** swings to close the laryngeal opening.
- Inhibition of the **respiratory center** → deglutition apnea

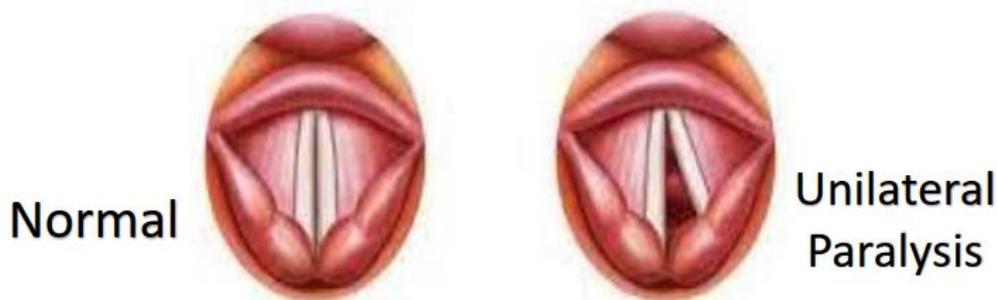

**3- Allow passage of food to the stomach through:**

- Contraction of the **superior constrictor muscle** of the pharynx.
- This contraction **spreads downward** as a rapid peristalsis along the esophagus.

**NB:**

- **Vocal cords paralysis** may be caused by damage of the supplying laryngeal nerves as during **neck surgery** → **Aspiration** (food and drink going into the airway) → **Pneumonia and lung infections.**
- Large volumes of **vomit** is expelled from the stomach into the pharynx in **some surgical operations.**
- **Paralysis of the swallowing mechanism** occurs when patients are in a state of **deep anesthesia.**
- As a result, some patients **may choke** on their own vomitus.

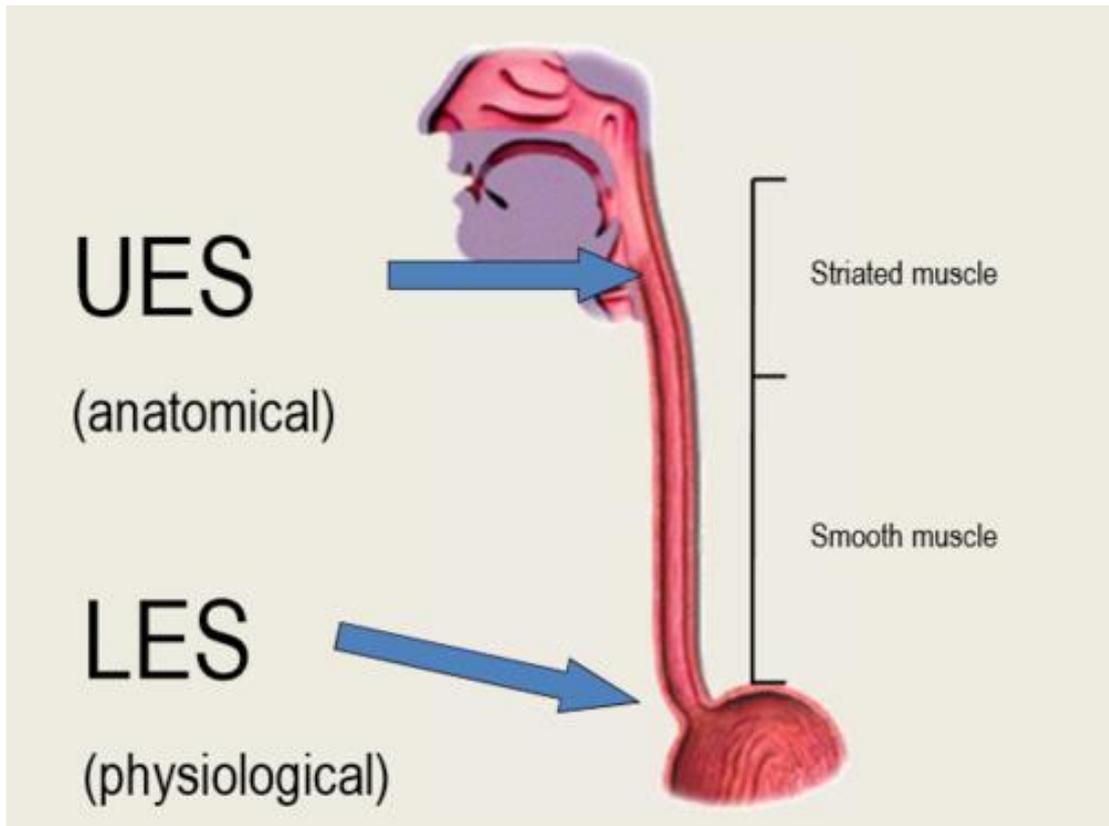

**C) Esophageal stage:**

- Esophagus conduct food from the pharynx to the stomach.
- It is a muscular tube about 20cm long.
- **The esophagus has two types of peristaltic movements:**

1- Primary peristalsis:	2- Secondary peristalsis:
<ul style="list-style-type: none"><li>• Continuation of the contraction of the <b>superior constrictor muscle</b> of the pharynx.</li><li>• it's coordinated by <b>vagus</b></li></ul>	<ul style="list-style-type: none"><li>• Caused by presence of food in esophagus due to <b>failure of</b> primary peristalsis to move all food.</li><li>• Caused by stimulation of <b>enteric nervous system</b></li></ul>

▪ Esophageal sphincters:

	<i>Upper esophageal sphincter (UES)</i>	<i>Lower esophageal sphincter (LES)</i>
<b>During rest</b>	<b>Contracted</b> → prevents entrance of <b>air</b> into the stomach during breathing.	<b>Contracted</b> → to prevent regurgitation of the <b>gastric acid</b> into the lower end of the esophagus.
<b>During swallowing</b>	<b>Relaxed</b> → until food passes then it contracts.	<b>Relaxed</b> → to pass food into the stomach.

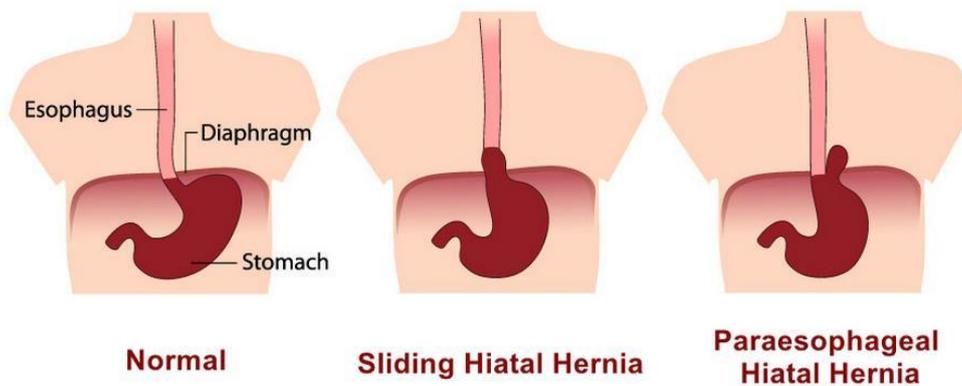

## Gastro-oesophageal reflux disease (GERD)

- **Decrease** The tone of LES → **GERD**
- **Causes:**
  - **Food:** e.g. Fat, tea, coffee, chocolate.
  - **Abnormal position of the sphincter:**
    - As in case of Hiatus hernia, in which the LES is present **intra-thoracic** (Normally in the **abdominal cavity**).

GENERAL SURGERY

### Hiatal (Hiatus) Hernia

## Achalasia of the cardia

- **Increase** The tone of LES → **Achalasia** of the cardia.

<b>Causes:</b>	<ul style="list-style-type: none"> <li>• LES <b>doesn't relax</b> during swallowing &amp; food accumulates in esophagus.</li> </ul>
<b>Symptoms:</b>	<ul style="list-style-type: none"> <li>• <b>Dysphagia</b> to both liquid and solid food.</li> </ul>
<b>Treatment:</b>	<ul style="list-style-type: none"> <li>• <b>Ballon dilatation.</b></li> <li>• <b>Myotomy.</b></li> <li>• injection of <b>botulinum toxin</b> into the LES.</li> </ul>
